### 1. Motivation

Italia**domani** 

**Detailed simulation** of the interaction between the traversing particles and the LHCb active volumes is the major consumer of CPU resources. During the LHC Run2, the LHCb experiment has spent **more than 90% of the pledged CPU time** to simulate events of interest. Matching the upcoming and future demand for simulated samples means that the development of **faster simulation options** is critical.

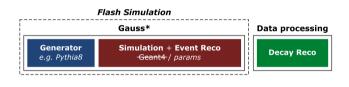

#### 2. Fast simulation VS. flash simulation

**Detailed simulation** relies on Geant4 to reproduce the radiation-matter interactions that are computed within Gauss\*, the LHCb simulation software.

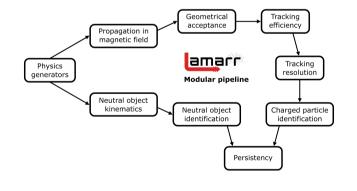

**Fast simulation** techniques aim to speed up the Geant4-based simulation production by parameterizing the energy deposits instead of relying on physics models.

Flash (or Ultra-Fast) simulation strategies aim to directly transform generator-level particles into analysis-level reconstructed objects.

## 3. What is Lamarr?

**Lamarr** is the novel flash-simulation framework of LHCb, able to offer the fastest option to produce simulated samples. Lamarr consists of a **pipeline of** (ML-based) **modular parameterizations** designed to replace both the simulation and reconstruction steps.

The Lamarr pipeline can be split in two chains:

- a branch treating charged particles relying on tracking and particle identification models;
- a branch facing the particle-to-particle correlation problem innate in the neutral objects reconstruction.

## 4. Models under the k-to-k hypothesis

Assuming the existence of an **unambiguous** (k-to-k) **relation** between generated particles and reconstructed objects, the high-level detector response can be modeled in terms of **efficiency** and **"resolution"** (i.e., analysis-level quantities):

- <u>Efficiency:</u> Deep Neural Networks (DNN) trained to perform classification tasks so that they can be used to parameterize the fraction of "good" candidates (e.g., accepted, reconstructed, or selected).
- Resolution: Conditional Generative Adversarial Networks (GAN) trained on detailed simulated samples to parameterize the high-level response of LHCb detector (e.g., reconstruction errors, differential log-likelihoods, or multivariate classifier output).

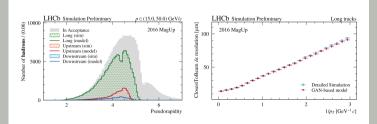

#### 5. Charged particles pipeline: the tracking system

Lamarr parameterizes the high-level response of the **LHCb tracking system** relying on the following models:

- propagation: approximates the trajectory of charged particles through the dipole magnetic field → parametric model;
- geometrical acceptance: predicts which of the generated tracks lay within a sensitive area of the detector → DNN model;
- tracking efficiency: predicts which of the generated tracks in the acceptance are properly reconstructed by the detector 

  DNN model;
- tracking resolution: parameterizes the errors introduced by the reconstruction algorithms to the track parameters 

   GAN model;
- covariance matrix: parameterizes the uncertainties assessed by the Kalman filter procedure → GAN model.

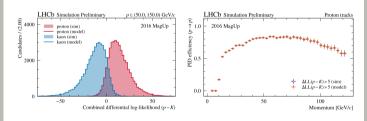

Validation plots for the DNN-based model of the tracking efficiency (left) and the GAN-based model of the spatial tracking resolution (right).

# 6. Charged particles pipeline: the PID system

Lamarr parameterizes the high-level response of the  $\textbf{LHCb\ PID\ system}$  relying on the following models:

- RICH PID: parameterizes DLLs resulting from the RICH detectors → GAN model;
- MUON PID: parameterizes likelihoods resulting from the MUON system  $\rightarrow$  GAN model;
- isMuon: parameterizes the response of a FPGA-based criterion for muon loose boolean selection → DNN model;
- Global PID: parameterizes the global high-level response of the PID system, consisting of CombDLLs and ProbNNs → GAN model.

Lamarr provides separated models for **muons**, **pions**, **kaons**, and **protons** for each PID set of variables.

Validation plots for the proton-kaon separation parameterized with the GAN-based models of the Global PID response in terms of distributions (left) and proton selection efficiency (right).

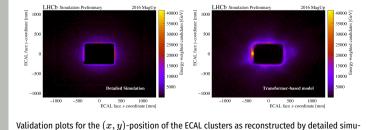

## 7. Neutral particles pipeline: the ECAL detector

The flash simulation of the LHCb ECAL detector is not trivial task:

- bremsstrahlung radiation, converted photons, or merged  $\pi^0$  may lead to have n generated particles responsible for m reconstructed objects (in general, with  $n \neq m$ );
- the  $\it particle-to-particle\ correlation\ problem\$  limits the validity of strategies used for modeling the unambiguous  $\it k$ -to- $\it k$  detector response.

To parameterize a generic n-to-m response of the ECAL detector, solutions inspired by the natural language **translation problem** are currently under investigation:

- the aim is to define an **event-level description** of the ECAL response;
- assuming ordered sequences of photons/clusters, the problem can be modeled with a *Transformer* model;
- complying with the problem topology, the ECAL response can be modeled with a Grapha Neural Network (GNN) model

lation (left) and a Transformer-based model (right). Each bin entry is properly weighted to include also the energy signature.

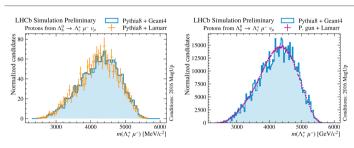

#### 8. Validation campaign

Lamarr provides the high-level response of the LHCb detector by relying on a **pipeline of** (subsequent) **ML-based modules**. To validate the charged particles chain, the distributions of a set of **analysis-level** reconstructed quantities resulting from Lamarr have been compared with that obtained from detailed simulation for  $\Lambda_b^0 \to \Lambda_c^+ \mu^- X$  decays with  $\Lambda_c^+ \to p K^- \pi^+$ .

The deployment of the ML-based models follows a **transcompilation approach** based on **scikinC**. The models are translated to C files, compiled as *shared objects*, and then dynamically linked in the LHCb simulation software (Gauss).

The integration of Lamarr with Gauss enables:

- interface with all the **LHCb-tuned physics generators** (e.g., Pythia8, EvtGen);
- compatibility with the distributed computing middleware and production environment;
- providing ready-to-use datasets for centralized analysis.

Validation plots for the  $\Lambda_c^+$  mass obtained from Pythia8 (left) and particle-gun (right) generators by Lamarr VS. detailed simulation. Reproduced from <u>LHCB-FIGURE-2022-014</u>.

## 9. Preliminary timing studies

Overall time needed for producing simulated samples has been analyzed for detailed simulation (Geant4-based) and Lamarr. When Lamarr is employed, the generation of particles from collisions (e.g., with Pythia8) becomes the new **maior CPU consumer**.

Lamarr allows to reduce the CPU cost for the simulation phase of (at least) **two-order-of-magnitude**. Further timing will require speeding up the generators.

**Detailed simulation:** Pythia8 + Geant4 1M events @  $2.5 \text{ kHS}06.\text{s/event} \simeq 80 \text{ HS}06.\text{y}$ 

Flash simulation: Pythia8 + Lamarr 1M events @ 0.5 kHS06.s/event  $\simeq$  15 HS06.y

Flash simulation: Particle Gun + Lamarr 100M events @ 1 HS06.s/event  $\simeq$  4 HS06.y

# 10. The ICSC project

TBA

### 11. Conclusions and outlook

Great effort is ongoing to put a **fully parametric simulation** of the LHCb experiment into production, aiming to reduce the pressure on computing resources.

DNN-based and GAN-based models succeed in describing the high-level response of the LHCb tracking and PID detectors for **charged particles**. Work is still required to parameterize the response of the ECAL detector due to the **particle-to-particle correlation problem**.

Future development Lamarr aims to support both integration within the LHCb software stack and its use as a **stand-alone** package.

### Acknowledgements

The work presented in this contribution is performed in the framework of Spoke 0 and Spoke 2 of the ICSC project - *Centro Nazionale di Ricerca in High Performance Computing, Big Data and Quantum Computing,* funded by the NextGenerationEU European initiative through the Italian Ministry of University and Research, PNRR Mission 4, Component 2: Investment 1.4, Project code CN00000013 - CUP I53C21000340006.
